This element is primarily the engine that equates sequences of timing pulses into positioning (quantity of turning) of all the hands. Typical motions were mechanically run, while modern ones function digitally, with the timing pulses generated by a quartz crystal.

The pulse stream is partitioned down into specific seconds, setting off the "tick" of a shaft to which the used is affixed. Further subdivision manages the activity of the hr and also minute hands, also affixed to concentric shafts. The shaft real estate is also the means for affixing the motor to the instance.

The threaded part of the shaft real estate needs to extend beyond the mounting opening by around 1/8". You could compensate for a better protuberance with shimming washers, but you cannot make up for one too brief. The activity is protected to the clock confront with a hex nut. Requirement clock motions are made for wrist watches less than approximately 14" in size. However they do not have the torque to turn the hands for bigger clocks because the extra length includes too much weight. In such a situation you should buy a high-torque version of the electric motor.
